 - Generic Construction

Identity-based Cryptography

- Key generation centre (KGC) generates public parameters and master secret.
- KGC gives private keys to users based on their *identity*.
- Identities may be names, email addresses etc.
E.g “bob@example.com”, “James Birkett”
- Sender uses an identity to encrypt.

Attribute-based Cryptography

- KGC gives private keys to users based on their *attributes*.
- Attributes are boolean values.
E.g “CS_department=true”, “Professor=true”,
“Student=false”
- The list of attributes is fixed at setup.
- Sender uses an access structure to encrypt.

- Access structures limited to AND, OR and threshold operations.

Predicate-based Cryptography

- Generalises attributes to credentials.
- Credentials are name-value pairs.
E.g “Department=CS”, “Department=Maths”
- The list of credentials need not be fixed at setup.
- More complex access structures available, e.g equality, subset or comparison operations as well as AND, OR and threshold.
- We call these access structures *predicates*, $\Phi(C)$.

Relationship

- Attribute-based cryptography is a special case of Predicate-based cryptography.
- Our model and generic construction handles both.

Therapy

With the Society of Secretive Psychologists.

Alice Needs:

- A registered psychologist.
- A private channel.
- Anonymity.

Bob Needs:

- A private channel.
- Proof of insurance.

Therapy

How Predicate-Based Key Exchange Could Help

Predicate-based Key Exchange

- If you do not need anonymity (credential-privacy) then you do not need predicate-based key exchange!
- Instead you may simply present a list of credentials signed by the trusted third party.

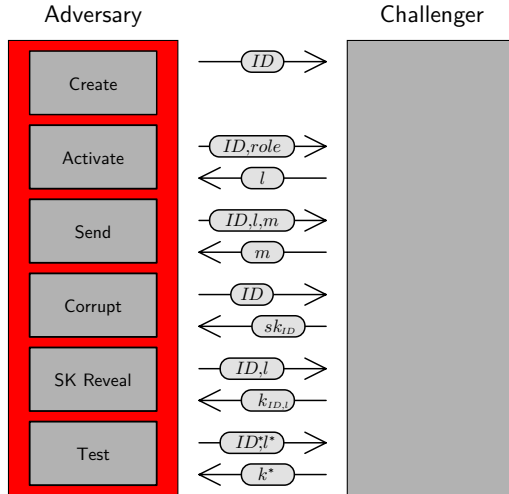

Outline

- 1 Background
 - Cryptographic Primitives
 - Key Exchange
- 2 Motivation
 - A Hypothetical Example

 - **Security Model**
 - Generic Construction

Identity-based Key-Exchange Security

- Challenger maintains a list of users ID_1, \dots, ID_n .
- Each user has a secret key sk_{ID} .
- Each user U_{ID} maintains a list of sessions.
- Each session contains:
 - The ID of the peer ID' .
 - A list of messages exchanged, m_1, \dots, m_r .
 - A state variable.
 - (Possibly) a key $k_{ID,\ell}$.

Identity-based Key-Exchange Security (cont)

Separating credentials from addresses

- Unique identities incompatible with credential-privacy.
- Cannot direct messages using credentials.
- Instead use user numbers independent from credentials for addressing.

Addressing the Addressing Problem

Attempt 1

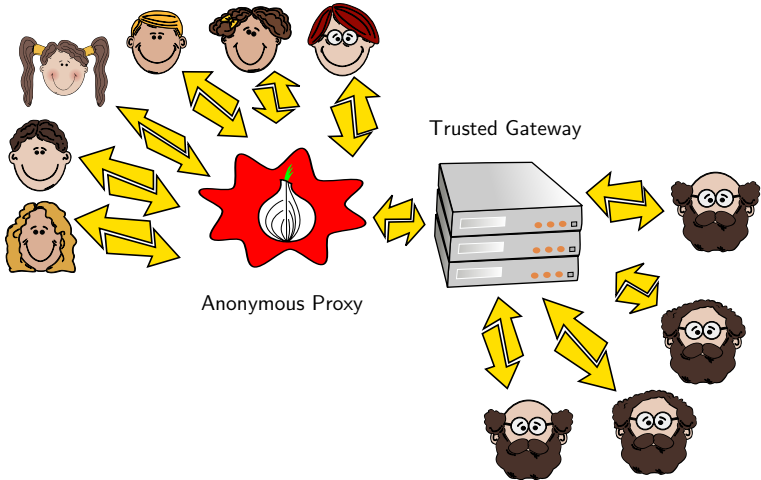

Addressing the Addressing Problem

Attempt 1

- Anonymous proxy servers / routing services may hide initiator's address.
- Initiator still needs to direct messages to the recipient.

Addressing the Addressing Problem

Attempt 2

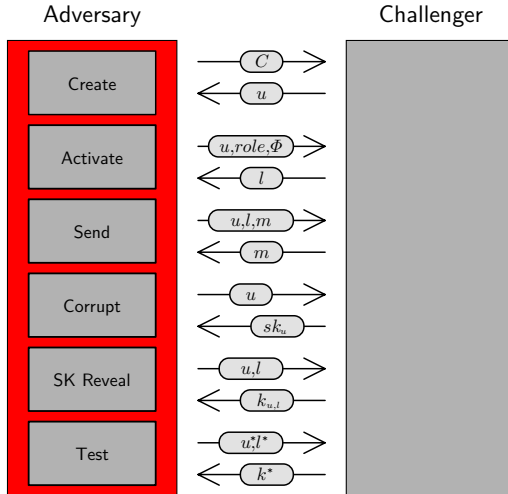

Addressing the Addressing Problem

Attempt 2

- Society of Secretive Psychologists operates their own trusted gateway.
- Gateway knows credentials of each psychologist.
- Gateway can choose psychologist satisfying a given predicate Φ .

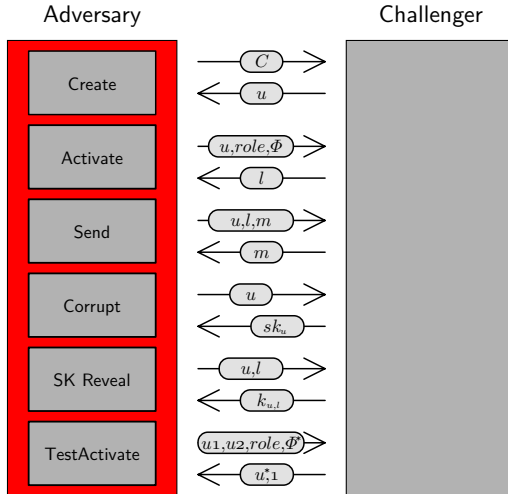

Session-Key Security

Session-Key Security (cont)

- Adversary may not corrupt any user such that $\Phi(C) = 1$.
 - Forward Security: adversary may corrupt user after the Test query.
- Adversary may not SKReveal u^*, l^* .
- Adversary may not SKReveal u, l if $s_{u,l}$ is a peer of s_{u^*,l^*} .

Credential Privacy

Credential Privacy (cont)

- Φ^* must satisfy $\Phi^*(C_{u_0}) = \Phi^*(C_{u_1})$
- Adversary may not Activate u^* .
- Adversary may not Corrupt U_{u_0} or U_{u_1} .
- Adversary may not SKReveal $u^*, 1$.
- Adversary may not SKReveal u, ℓ if $s_{u,\ell}$ is a peer of $s_{u^*,1}$.

Credential Privacy and Unlinkability

Credential Privacy

No user can determine anything about your credentials other than $\Phi(C)$, i.e. whether you satisfy their predicate.

Unlinkability

You cannot tell if two sessions are with the same person or not.

- Credential privacy implies Unlinkability.

Protocol Flow

$\Pi_{S,G}$ – Protocol flow	
Initiator	Responder
secret key sk_I responder predicate Φ_I	secret key sk_R initiator predicate Φ_R
$x \xleftarrow{R} \mathbb{Z}_q$ $X \leftarrow g^x$	
	$\xrightarrow{X, \Phi_I}$
	$y \xleftarrow{R} \mathbb{Z}_q$ $Y \leftarrow g^y$ $\sigma_R \leftarrow \text{Sign}(sk_R, (\text{resp}, X, \Phi_I, Y, \Phi_R), \Phi_I)$
	$\xleftarrow{Y, \Phi_R, \sigma_R}$
If $\neg \text{Verify}((\text{resp}, X, \Phi_I, Y, \Phi_R), \Phi_I, \sigma_R)$: status \leftarrow Failed Abort $\sigma_I \leftarrow \text{Sign}(sk_I, (\text{init}, X, \Phi_I, Y, \Phi_R, \sigma_R), \Phi_R)$ $Z \leftarrow Y^x$ $k \leftarrow H(X, \Phi_I, Y, \Phi_R, Z)$ status \leftarrow Established	
	$\xrightarrow{\sigma_I}$
	If $\neg \text{Verify}((\text{init}, X, \Phi_I, Y, \Phi_R, \sigma_I), \Phi_R, \sigma_I)$: status \leftarrow Failed Abort $Z \leftarrow X^y$ $k \leftarrow H(X, \Phi_I, Y, \Phi_R, Z)$ status \leftarrow Established

Summary

- Existing key-exchange models identify credentials with addresses.
- Predicate-based models must find an alternative to this.
- Predicate-based key exchange is only useful if you require credential-privacy.

- Future work
 - Adapt the model to include state-reveal or ephemeral-key-reveal queries.
 - Develop constructions which are secure against these queries.
